Real-Life Example

Generate

Sorting a **large stack of papers** (or a deck of cards) by date or name.

1. **Divide:** You split the unsorted stack into two smaller, more manageable piles.
2. **Conquer (Recursion):** You then sort each of those smaller piles *independently*. If a pile is still too big, you might split it again, and so on, until you have very small piles (e.g., 2-3 papers) that are easy to sort.
3. **Merge:** Once you have two *sorted* sub-piles, you merge them back together by taking the next correct paper from the top of either pile until you have one complete, sorted stack.
